#### Abstract

Hard water can cause many problems including scaling and excessive soap consumption. In the United States, hard water is mostly found in the mid western and western states. It ranges between $120-250 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$ or beyond $250 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$ for very hard waters. The acceptable water hardness range is between $60-120 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$. A water softening experiment was conducted in replicate to observe the changes in parameters such as total hardness, calcium hardness, magnesium hardness, alkalinity and pH with varying dosages of lime. A lime dosage range of $30-180 \%$ of the stoichiometric amount was chosen for the experiments. The sample used was groundwater from an East Lansing well which had a total hardness of $332 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$. Results indicated that an increase in lime dosage upto $90 \%$ caused a decrease in total hardness, alkalinity, magnesium hardness and calcium hardness concentrations. However, for a lime dosage beyond $120 \%$, the total hardness, alkalinity, and calcium hardness concentrations increased while magnesium hardness concentration decreased to lower values. The pH continually increased for a lime dosage between $30 \%$ and $180 \%$.

## INTRODUCTION

Hard water is the most common water quality problem reported by consumers throughout the United States. More than 60 percent of the Earth's water is ground water and hard water is found in more than $85 \%$ of the country. The water travels through rocks and soil picking up minerals including calcium and magnesium, ions which produce hard water. (Water Review, Consumer report, 1990).

Hard water interferes with almost every cleaning task from laundering and dishwashing to bathing and personal grooming (IANR, Water Quality 1996). Clothes laundered in hard water may look dingy and feel harsh and scratchy. Dealing with hard water problems in the home can be a nuisance. In addition, hard water affects the amount of soap and detergent necessary for cleaning. Soap used in hard water combines with the minerals to form a sticky soap curd. Some synthetic detergents are less effective in hard water because the active ingredient is partially inactivated by hardness, even though it stays dissolved. Bathing with soap in hard water leaves a film of sticky soap curd on the skin. The film may prevent removal of dirt and bacteria. Soap curd interferes with the return of skin to its normal, slightly acid condition, and may lead to irritation. Soap curd on hair may make it dull, lifeless and difficult to manage.

Hard water also contributes to inefficient and costly operation of water treatment equipment. Heated hard water forms a scale of calcium and magnesium minerals that can contribute to the inefficient operation or failure of water treatment equipment. Pipes can become clogged with scale which reduces water flow and ultimately results in pipe replacement.

Hard water is not a health hazard. In fact, the National Research Council (National Academy of Sciences) states that drinking hard water generally contributes to the total calcium and magnesium needs in humans.

Water utilities struggling with source water that contains high amounts of calcium and/or magnesium often turn to lime softening to remove hardness. Raising treatment pH above 9.6 converts soluble calcium bicarbonate hardness to insoluble calcium carbonate. An increase in pH beyond 10.6 converts soluble magnesium bicarbonate to insoluble magnesium hydroxide. Aggressive magnesium removal often requires a treatment pH of 11 or higher, a process known as excess lime softening (Jones, C; et.al. 2005).

## Chemistry of Hardness Removal Process

During precipitation softening, calcium is removed form water in the form of $\mathrm{CaCO}_{3}$ precipitate and magnesium is removed as $\mathrm{Mg}(\mathrm{OH})_{2}$ precipitate (Frederick W. Pontius). The carbonic acid concentration present and the pH play an important role in the precipitation of these two solids. Carbonate hardness can be removed by the addition of hydroxide ions and raising the pH by which the bicarbonate ions are converted to carbonate form having a pH above 10 . Due to the increase in carbonate concentration, precipitates of calcium carbonate is formed. The remaining calcium, i.e. non carbonate hardness, cannot be removed by simple adjustment of pH . Therefore, soda ash (sodium carbonate) must be externally added to precipitate this remaining calcium. Magnesium is removed due to the precipitation of magnesium hydroxide. In the lime soda ash process, lime is added to raise the pH while sodium carbonate is added to provide a source of carbonate ion.

$$
\begin{equation*}
\mathrm{H}_{2} \mathrm{CO}_{3}+\mathrm{Ca}(\mathrm{OH})_{2} \rightarrow \mathrm{CaCO}_{3}+2 \mathrm{H}_{2} \mathrm{O} \tag{1}
\end{equation*}
$$

Eq.(1) is the neutralization reaction between $\mathrm{CO}_{2}$ carbonic acid and lime. This equation does not result any net change in water hardness. This also suggest that for each $\mathrm{mg} / \mathrm{L}$ of carbonic acid expressed as $\mathrm{CaCO}_{3}$ present, $1 \mathrm{mg} / \mathrm{L}$ of lime expressed as $\mathrm{CaCO}_{3}$ will be required for neutralization by knowing the stoichiometric ratios.

$$
\begin{equation*}
\mathrm{Ca}^{2+}+2 \mathrm{HCO}_{3}^{-}+\mathrm{Ca}(\mathrm{OH})_{2} \rightarrow 2 \mathrm{CaCO}_{3}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O} \tag{2}
\end{equation*}
$$

Eq.(2) presents the removal of calcium carbonate hardness. It also shows that for each molecule of calcium bicarbonate present, two carbonate ions can be formed by increasing the pH . This also suggest that for each $\mathrm{mg} / \mathrm{L}$ of calcium bicarbonate present, $1 \mathrm{mg} / \mathrm{L}$ of lime expressed as $\mathrm{CaCO}_{3}$ will be required for its removal by knowing the stoichiometric ratios between them.

$$
\mathrm{Ca}^{2+}+\left[\begin{array}{l}
\mathrm{SO}_{4}^{2-}  \tag{3}\\
2 \mathrm{Cl}^{-}
\end{array}\right]+\mathrm{Na}_{2} \mathrm{CO}_{3} \rightarrow \mathrm{CaCO}_{3}+2 \mathrm{Na}^{+}+\left[\begin{array}{l}
\mathrm{SO}_{4}^{2-} \\
2 \mathrm{Cl}^{-}
\end{array}\right]
$$

Eq.(3) reflects the removal of calcium noncarbonated hardness. The stoichiometric coefficient suggest that for each $\mathrm{mg} / \mathrm{L}$ of calcium noncarbonate hardness present, $1 \mathrm{mg} / \mathrm{L}$ of sodium carbonate expressed as $\mathrm{CaCO}_{3}$ will be required for its removal.
$\mathrm{Mg}^{2+}+2 \mathrm{HCO}_{3}+2 \mathrm{Ca}(\mathrm{OH})_{2} \rightarrow 2 \mathrm{CaCO}_{3}+\mathrm{Mg}(\mathrm{OH})_{2}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}$

Eq. (4) is similar to eq.(2). If the magnesium bicarbonate and lime are expressed as $\mathrm{CaCO}_{3}$, then the stoichiometric ratios suggest that for each $\mathrm{mg} / \mathrm{L}$ of magnesium bicarbonate hardness present, $2 \mathrm{mg} / \mathrm{L}$ of lime expressed as $\mathrm{CaCO}_{3}$ will be needed for its removal.
$\mathrm{Mg}^{2+}+\left[\begin{array}{l}\mathrm{SO}_{4}^{2-} \\ 2 \mathrm{Cl}^{-}\end{array}\right]+\mathrm{Ca}(\mathrm{OH})_{3} \rightarrow \mathrm{Mg}(\mathrm{OH})_{2}(\mathrm{~s})+\mathrm{Ca}^{+}+\left[\begin{array}{l}\mathrm{SO}_{4}^{2-} \\ 2 \mathrm{Cl}^{-}\end{array}\right]$

Eq. (5) represents the removal of magnesium noncarbonate hardness. If the magnesium noncarbonate hardness and lime are expressed as $\mathrm{CaCO}_{3}$, stoichiometric ratios suggest that for each $\mathrm{mg} / \mathrm{L}$ of magnesium noncarbonate hardness present, $1 \mathrm{mg} / \mathrm{L}$ of lime expressed as $\mathrm{CaCO}_{3}$ will be needed for its removal. Here no net change in the hardness level resulted as for each magnesium ion removed calcium ion is added.

Thus to complete the hardness removal process, sodium carbonate required to be added to precipitate the calcium as presented in the equation below.
$\mathrm{Ca}^{2+}+\left[\begin{array}{l}\mathrm{SO}_{4}^{2-} \\ 2 \mathrm{Cl}^{-}\end{array}\right]+\mathrm{Na}_{2} \mathrm{CO}_{3} \rightarrow \mathrm{CaCO}_{3}(\mathrm{~s})+2 \mathrm{Na}^{+}+\left[\begin{array}{l}\mathrm{SO}_{4}^{2-} \\ 2 \mathrm{Cl}^{-}\end{array}\right]$

## OBJECTIVE

The objective of the water softening experiment was to determine the effects of varying lime dosages on parameters such as total hardness, calcium hardness, magnesium hardness, alkalinity and pH .

## METHODS and MATERIALS

Very hard ground water was obtained from a well located in East Lansing provided by Joseph Nguyen. Initial sample characteristics such as pH , alkalinity, and total hardness are provided in Appendix 2. A lime, $\mathrm{Ca}(\mathrm{OH})_{2}$, stock solution of $10 \mathrm{mg} / \mathrm{mL}$ was prepared for dosing the sample with $30,60,90,120,150$ and 180 percent of the stoichiometric amount of lime. The jar test was executed with the conventional apparatus with six 2 -liter beakers (Appendix-2) mixing the groundwater with the various amounts of lime for 20 min at 30 rpm . The samples were then filtered through $0.45 \mu \mathrm{~m}$ filter and then titrated for total hardness, calcium hardness, and alkalinity. In addition pH and magnesium hardness were noted down. This experiment was done in replicate to compare results and determine the degree of experimental error. Detailed protocols for this experiment, including titrations and calculations, are available in the appendix.

## RESULTS and DISSCUSSION

## Run 1: Water Softening

Replicate 1: Variation of Hardness, Alkalinity and pH for varying Lime dosages

Figure 1: Variation of Hardness, Alkalinity and pH for varying Lime dosages (Run1)

Replicate runs for the water softening experiment evaluated parameters such as alkalinity, hardness and pH in response to varying lime dosages from $30 \%$ to $180 \%$ of the stoichiometric amount. In Run 1, the total hardness reached a minimum value of approximately $160 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$ for a lime dosage of $90 \%$ (fig.1). The calcium hardness first decreased in concentration to a minimum of $35 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$ for a lime dosage of $90 \%$ and then after that continued to increase in concentration with an increase of lime dosage. This increase in calcium hardness was observed due to the addition of excess lime and the absence of alkalinity caused by carbonates. The plateau between $60 \%$ and $90 \%$ of lime is due to the presence of extra alkalinity. Any excess lime added in this region converts bicarbonates to carbonates and those carbonates combine with the free calcium ions to form precipitates.

Magnesium hardness concentration decreased with the increasing dosage of lime. Alkalinity decreased to a minimum at approximately $90 \%$ of lime and increased thereafter. This is due to the addition of lime and the precipitation of species, which consumes alkalinity that causes the initial decrease. At lime dosages higher than $120 \%$, alkalinity increases due to an addition of excess lime. For every addition of lime, free
$\mathrm{OH}^{-}$ions are released, therefore an increase in $\mathrm{OH}^{-}$ions is responsible for an increase in pH.

## Run 2: Water Softening

Replicate 2: Variation of Hardness, Alkalinity and pH for various Lime dosages

Figure 2: Variation of Hardness, Alkalinity and pH for varying Lime dosages (Run2)

In Run 2, the total hardness reaches a minimum value of approximately $160 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$ for a lime dosage of $120 \%$ (fig.2). The calcium hardness concentration first decreases to a minimum of $35 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$ for a lime dosage of $60 \%$ and then starts to increase above a lime dosage of $90 \%$. This result was due to the addition of excess lime and the absence of alkalinity caused by carbonates. The plateau between $60 \%$ and $90 \%$ of lime was because of the presence of extra alkalinity. Any excess lime added in this region converts bicarbonates to carbonates and combine with the free calcium ions to form precipitates.

Magnesium hardness decreases with an increase in lime dosage and reaches a concentration of $30 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$, for a lime dosage of $180 \%$. This concentration indicates an approximate solubility limit of magnesium ions. In addition alkalinity decreased to a minimum around $90 \%$ of lime but increases thereafter. The trends observed in Run1 and Run 2 were in good correlation with each other.

Figure 3: Comparison of Replicate Runs

This plot is a comparative study of the data obtained from run 1 and run2. The data from each run have an $\mathrm{R}^{2}$ correlation of 0.90 for the parameters of this study. Hence, the experiment is reproducible and the trends observed for each parameter in response to varying lime dosages are in agreement with the expected trends.

## CONCLUSIONS

This experiment yielded the following conclusions:

- Calcium hardness concentrations decreased with an increase in lime dosage but concentrations increased at dosages higher than $90 \%$.
- Magnesium hardness decrease with an increase in lime dosage, especially when calcium hardness was increased (dosage higher than 90\%)
- Alkalinity decreased to a minimum value of approximately $135 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$ at a lime dosage of $90 \%$ and increased thereafter due to the addition of excess lime.
- pH increased with an increase in lime dosage due to the generation of free $\mathrm{OH}^{-}$ ions.
- The replicate runs conducted were in correlation with each other, thereby demonstrating reproducibility.

## APPENDIX 2 - Sample Calculation to Determine the Lime Dosage

Sample: Ground water
$\mathrm{pH}=7.72$
$\mathrm{Ca}^{2+}=200 \mathrm{mg} / \mathrm{L}$
$\mathrm{Mg}^{2+}=132 \mathrm{mg} / \mathrm{L}$
Temperature $=20^{\circ} \mathrm{C}$
Alkalinity $=311 \mathrm{mg} / \mathrm{L}$
Total Hardness $=332 \mathrm{mg} / \mathrm{L}$
Carbonate Hardness $=$ Alkalinity $=311 \mathrm{mg} / \mathrm{L} \mathrm{CaCO}_{3}$
Non Carbonate hardness $=$ Total hardness- Alkalinity $=21 \mathrm{mg} / \mathrm{L} \mathrm{CaCO}_{3}$
From the above values we know that it is an excess lime soda -ash process

Step1: Assume $\mathbf{p H}=7$, so all alkalinity is in the bicarbonate form
a) $\left[\mathrm{HCO}_{3}\right]=311 \times\left(\frac{61}{50}\right) \times\left(\frac{1}{1000}\right) \times\left(\frac{1}{61}\right)=6.22 \times 10^{-3} \mathrm{~mol} / \mathrm{L}$
b) $\mathrm{K}_{1}=10^{14.8435-3404.71 / 293-0.032786 \text { (293) }}$

$$
\mathrm{K}_{1}=4.26 \times 10^{-7}
$$

$\mathrm{K}_{2}=10^{6.498-2909.39 / 293-0.02379(293)}$

$$
\mathrm{K}_{2}=3.97 \times 10^{-11}
$$

c) $\alpha_{1}=\frac{1}{1 \times 10^{-7} / K_{1}+1+K_{2} / 1 \times 10^{-7}}$

$$
\begin{aligned}
& =\frac{1}{1 \times 10^{-7} / 4.26 \times 10^{-7}+1+3.97 \times 10^{-11} / 1 \times 10^{-7}} \\
& =0.81
\end{aligned}
$$

d) $\mathrm{C}_{\mathrm{T}}=\frac{6.22 \times 10-3}{0.81}=7.679 \times 10^{-3} \mathrm{~mol} / \mathrm{L}$
e) $\left[\mathrm{HCO}_{3}{ }^{*}\right]=7.679 \times 10^{-3}-6.22 \times 10^{-3}=1.477 \times 10^{-3} \mathrm{~mol} / \mathrm{L}$
$\left[\mathrm{HCO}_{3}{ }^{*}\right]=1.477 \times 10^{-3} \mathrm{~mol} / \mathrm{L} \times 62 \mathrm{~g} / \mathrm{mol}=0.0915 \mathrm{~g} / \mathrm{L}=91.5 \mathrm{mg} / \mathrm{L}$
$\left[\mathrm{HCO}_{3}{ }^{*}\right]=147.7 \mathrm{mg} / \mathrm{L} \mathrm{CaCO}_{3}$

## Step2:

Total Hardness $=332 \mathrm{mg} / \mathrm{L}$
$\mathrm{Ca}^{2+}$ Carbonate Hardness $=200 \mathrm{mg} / \mathrm{L}$
$\mathrm{Ca}^{2+}$ Non Carbonate Hardness $=0 \mathrm{mg} / \mathrm{L}$
$\mathrm{Mg}^{2+}$ Carbonate Hardness $=311-200=111 \mathrm{mg} / \mathrm{L}$
$\mathrm{Mg}^{2+}$ Non Carbonate Hardness $=332-311=21 \mathrm{mg} / \mathrm{L}$

## Step3:

## Lime Dosage:

$147.7+200+2(111)+21=590.7 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$
$590.7 \mathrm{X}(37 / 50)=437.118 \mathrm{mg} / \mathrm{L}$ as $\mathrm{Ca}(\mathrm{OH})_{2}$

## Soda Ash dose:

$=0+21=21 \mathrm{mg} / \mathrm{L}$ as $\mathrm{CaCO}_{3}$
Soda ash dose $=21 \times \frac{53}{50}=22.26 \mathrm{mg} / \mathrm{L}$ as $\mathrm{Na}_{2} \mathrm{CO}_{3}$

## APPENDIX 3 - Water Softening and alkalinity Protocol

## Water Softening Protocol

## TRIAL RUN:

1. Prepare a Lime stock of $10 \mathrm{mg} / \mathrm{mL}$
2. Prepare 0.1 M EDTA stock
3. Using ground water samples measure Total hardness, Calcium hardness, Magnesium hardness, Alkalinity, pH and Temperature
a. Total hardness, Calcium hardness and Alkalinity protocols attached at the end of this document.
4. Determine the appropriate water softening process:
a. i.e. East Lansing well water= excess lime soda-ash
5. Calculate and add lime dosage for $100 \%$ stoichiometric amount to a liter of ground water
a. Use AWWA equations for dosage calculation
6. Conduct flocculation for 20 min at 30 RPM
7. Filter the entire sample through 0.45 uL filter (smooth side of filter facing down in the funnel)
8. Collect supernatant and measure Alkalinity, Calcium and Total hardness and pH
9. Calculate Magnesium hardness

RUN 1 \& 2:

1. Calculate and add lime dosage for $30,60,90,120,150$, and $180 \%$ of the stoichiometric amount to a liter of ground water.
a. Use AWWA equations for dosage calculation
2. Conduct flocculation for 20 min at 30 RPM
3. Filter the entire sample through 0.45 uL filter (smooth side down in the funnel)
4. Collect supernatant and measure Alkalinity, Calcium and Total hardness and pH
5. Calculate Magnesium hardness
6. Repeat experiment to determine degree of experimental error

## ALKALINITY PROTOCOL:

1. Use pH 7.0 buffer and adjust the pH meter to 7.0 . Use pH 4.0 buffer and adjust the pH meter to 4.0 .
2. Titrate 100 mL of sample with 0.02 N H2SO4 to obtain pH 4.5 by vigorously stirring towards the end of the titration step. This is done in order to break the surface and to obtain rapid equilibrium between CO 2 in solution and CO 2 in the atmosphere.
3. Total Alkalinity is measured as CaCO 3 in $\mathrm{mg} / \mathrm{L}=(\mathrm{ml}$ of titrant $) \mathrm{X} 10$

## To prepare 0.02 N H2SO4, Use the following formula:

Nf * $\mathrm{Vf}=\mathrm{Ni}{ }^{*} \mathrm{Vi}$
Where:
Nf: Final normality desired
Vf: Final total volume
Ni: Initial normality
Vi: Initial volume

## TOTAL HARDNESS:

1. Take 25 mL of sample and add 25 mL of DI water
2. Add 1 mL of hardness buffer and measure pH

- Ideal pH for reaction is above 10

3. Add a scoop of Erichrome Black T indicator

- The solution will turn pink

4. Titrate 0.1 M EDTA until a permanent blue color appears

- This is when $\mathrm{Ca}^{++}$and $\mathrm{Mg}^{++}$ions complex w/EDTA

5. Total Hardness= Volume of titrant ${ }^{*} 1 *(1000 /$ vol. of sample $)$

## $\mathbf{C a}^{++}$HARDNESS:

1. Take 25 mL of sample and add 25 mL of DI water
2. Add 2 mL 8 N NaOH solution and measure pH

- pH ideally above 10 , usually 12 or 13

3. Add a scoop of Erichrome Blue Black R indicator

- The solution will turn pink

4. Titrate 0.01 N EDTA until a permanent blue color appears
5. Calcium Hardness=Volume of titrant* $1 *(1000 / \mathrm{vol}$. of sample $)$

# Total Hardness $=\mathbf{C a}^{++}$Hardness $+\mathbf{M g}^{++}$Hardness 

## Carbonate Hardness=Alkalinity

## Non-carbonate Hardness=Total Hardness - Alkalinity

## APPENDIX 4 - Pictures
