Human adenovirus removal by hollow fiber membranes: Effect of
membrane fouling by suspended and dissolved matter

Accepted for publication in the Journal of Membrane Science on February 21, 2015.

Published article DOI: 10.1016/j.memsci.2015.02.028

Figure S1: Variability of permeate flow rate during a filtration experiment. The data set is for a filtration test with SiO$_2$ colloids as the sole foulant.
Figure S2: Virus removal as a function of time during filtration of suspension of SiO$_2$ microspheres, solution of humic acid, and a mixture of SiO$_2$/HA mixture by three membranes of different nominal pore sizes: a) 0.04 µm, b) 0.22 µm, and c) 0.45 µm. Circled numbers mark experimental stages (see section 2.4). Arrows indicate how virus removal changed after foulants were introduced into the membrane feed.
Figure S3: Lack of correlation between virus removal and fouling. The extent of fouling is quantified as the average rate of transmembrane pressure increase due to fouling.
