LM2576/LM2576HV Series
SIMPLE SWITCHER® 3A Step-Down Voltage Regulator

General Description
The LM2576 series of regulators are monolithic integrated circuits that provide all the active functions for a step-down (buck) switching regulator, capable of driving 3A load with excellent line and load regulation. These devices are available in fixed output voltages of 3.3V, 5V, 12V, 15V, and an adjustable output version.

Requiring a minimum number of external components, these regulators are simple to use and include internal frequency compensation and a fixed-frequency oscillator.

The LM2576 series offers a high-efficiency replacement for popular three-terminal linear regulators. It substantially reduces the size of the heat sink, and in some cases no heat sink is required.

A standard series of inductors optimized for use with the LM2576 are available from several different manufacturers. This feature greatly simplifies the design of switch-mode power supplies.

Other features include a guaranteed ±4% tolerance on output voltage within specified input voltages and output load conditions, and ±10% on the oscillator frequency. External shutdown is included, featuring 50 µA (typical) standby current. The output switch includes cycle-by-cycle current limiting, as well as thermal shutdown for full protection under fault conditions.

Features
- 3.3V, 5V, 12V, 15V, and adjustable output versions
- Adjustable version output voltage range, 1.23V to 37V (57V for HV version) ±4% max over line and load conditions
- Guaranteed 3A output current
- Wide input voltage range, 40V up to 60V for HV version
- Requires only 4 external components
- 52 kHz fixed frequency internal oscillator
- TTL shutdown capability, low power standby mode
- High efficiency
- Uses readily available standard inductors
- Thermal shutdown and current limit protection
- P+ Product Enhancement tested

Applications
- Simple high-efficiency step-down (buck) regulator
- Efficient pre-regulator for linear regulators
- On-card switching regulators
- Positive to negative converter (Buck-Boost)

**Note 1:** Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but do not guarantee specific performance limits. For guaranteed specifications and test conditions, see the Electrical Characteristics.

**Note 2:** All limits guaranteed at room temperature (standard type face) and at temperature extremes (bold type face). All room temperature limits are 100% production tested. All limits at temperature extremes are guaranteed via correlation using standard Statistical Quality Control (SQC) methods.

**Note 3:** External components such as the catch diode, inductor, input and output capacitors can affect switching regulator system performance. When the LM2576/LM2576HV is used as shown in the Figure 2 test circuit, system performance will be as shown in system parameters section of Electrical Characteristics.

**Note 4:** Output pin sourcing current. No diode, inductor or capacitor connected to output.

**Note 5:** Feedback pin removed from output and connected to 0V.

**Note 6:** Feedback pin removed from output and connected to +12V for the Adjustable, 3.3V, and 5V versions, and +25V for the 12V and 15V versions, to force the output transistor OFF.

**Note 7:** $V_{IN} = 40V$ (60V for high voltage version).

**Note 8:** Junction to ambient thermal resistance (no external heat sink) for the 5 lead TO-220 package mounted vertically, with 1/8 inch leads in a socket, or on a PC board with minimum copper area.

**Note 9:** Junction to ambient thermal resistance (no external heat sink) for the 5 lead TO-220 package mounted vertically, with 1/4 inch leads soldered to a PC board containing approximately 4 square inches of copper area surrounding the leads.

**Note 10:** If the TO-263 package is used, the thermal resistance can be reduced by increasing the PC board copper area thermally connected to the package. Using 0.5 square inches of copper area, $\theta_{JA} = 50^\circ C$/W, with 1 square inch of copper area, $\theta_{JA} = 37^\circ C$/W, and with 1.6 or more square inches of copper area, $\theta_{JA} = 32^\circ C$/W.

**Note 11:** The oscillator frequency reduces to approximately 11 kHz in the event of an output short or an overload which causes the regulated output voltage to drop approximately 40% from the nominal output voltage. This self protection feature lowers the average power dissipation of the IC by lowering the minimum duty cycle from 5% down to approximately 2%.

Test Circuit and Layout Guidelines

As in any switching regulator, layout is very important. Rapidly switching currents associated with wiring inductance generate voltage transients which can cause problems. For minimal inductance and ground loops, the length of the leads indicated by heavy lines should be kept as short as possible.

<tbody>
<tr>
<td><strong>Given:</strong> V&lt;sub&gt;OUT&lt;/sub&gt; = Regulated Output Voltage (3.3V, 5V, 12V, or 15V) V&lt;sub&gt;IN&lt;/sub&gt;(Max) = Maximum Input Voltage I&lt;sub&gt;LOAD&lt;/sub&gt;(Max) = Maximum Load Current</td>
<td><strong>Given:</strong> V&lt;sub&gt;OUT&lt;/sub&gt; = 5V V&lt;sub&gt;IN&lt;/sub&gt;(Max) = 15V I&lt;sub&gt;LOAD&lt;/sub&gt;(Max) = 3A</td>
</tr>
<tr>
<td>1. <strong>Inductor Selection (L1)</strong> A. Select the correct Inductor value selection guide from Figures 3, 4, 5 or Figure 6. (Output voltages of 3.3V, 5V, 12V or 15V respectively). For other output voltages, see the design procedure for the adjustable version. B. From the inductor value selection guide, identify the inductance region intersected by V&lt;sub&gt;IN&lt;/sub&gt;(Max) and I&lt;sub&gt;LOAD&lt;/sub&gt;(Max), and note the inductor code for that region. C. Identify the inductor value from the inductor code, and select an appropriate inductor from the table shown in Figure 3. Part numbers are listed for three inductor manufacturers. The inductor chosen must be rated for operation at the LM2576 switching frequency (52 kHz) and for a current rating of 1.15 x I&lt;sub&gt;LOAD&lt;/sub&gt;. For additional inductor information, see the inductor section in the Application Hints section of this data sheet.</td>
<td>1. <strong>Inductor Selection (L1)</strong> A. Use the selection guide shown in Figure 4. B. From the selection guide, the inductance area intersected by the 15V line and 3A line is L100. C. Inductor value required is 100 µH. From the table in Figure 3. Choose AIE 415-0930, Pulse Engineering PE92108, or Renco RL2444.</td>
</tr>
<tr>
<td>2. <strong>Output Capacitor Selection (C&lt;sub&gt;OUT&lt;/sub&gt;)</strong> A. The value of the output capacitor together with the inductor defines the dominate pole-pair of the switching regulator loop. For stable operation and an acceptable output ripple voltage, (approximately 1% of the output voltage) a value between 100 µF and 470 µF is recommended. B. The capacitor’s voltage rating should be at least 1.5 times greater than the output voltage. For a 5V regulator, a rating of at least 8V is appropriate, and a 10V or 15V rating is recommended. Higher voltage electrolytic capacitors generally have lower ESR numbers, and for this reason it may be necessary to select a capacitor rated for a higher voltage than would normally be needed.</td>
<td>2. <strong>Output Capacitor Selection (C&lt;sub&gt;OUT&lt;/sub&gt;)</strong> A. C&lt;sub&gt;OUT&lt;/sub&gt; = 680 µF to 2000 µF standard aluminum electrolytic. B. Capacitor voltage rating = 20V.</td>
</tr>
<tr>
<td>3. <strong>Catch Diode Selection (D1)</strong> A. The catch-diode current rating must be at least 1.2 times greater than the maximum load current. PROCEDURE (Adjustable Output Voltage Versions)

2. Inductor Selection (L1) A. Calculate the inductor Volt microsecond constant, $E \cdot T (V \cdot \mu s)$, from the following formula:

$$E \cdot T = \frac{(V_{IN} - V_{OUT})}{V_{IN}} \cdot \frac{1000}{F \ (kHz)} \ (V \cdot \mu s)$$

B. Use the $E \cdot T$ value from the previous formula and match it with the $E \cdot T$ number on the vertical axis of the Inductor Value Selection Guide shown in Figure 7. C. On the horizontal axis, select the maximum load current. D. Identify the inductance region intersected by the $E \cdot T$ value and the maximum load current value, and note the inductor code for that region. E. Identify the inductor value from the inductor code, and select an appropriate inductor from the table shown in Figure 9. Part numbers are listed for three inductor manufacturers. The inductor chosen must be rated for operation at the LM2576 switching frequency (52 kHz) and for a current rating of $1.15 \times I_{LOAD}$. For additional inductor information, see the inductor section in the application hints section of this data sheet.

EXAMPLE (Adjustable Output Voltage Versions)

2. Inductor Selection (L1) A. Calculate $E \cdot T (V \cdot \mu s)$

$$E \cdot T = (25 - 10) \cdot \frac{1000}{25} \cdot \frac{1}{52} = 115 \ V \cdot \mu s$$

B. $E \cdot T = 115 \ V \cdot \mu s$ C. $I_{LOAD}(Max) = 3A$ D. Inductance Region = H150 E. Inductor Value = 150 $\mu H$ Choose from AIE part #415-0936 Pulse Engineering part #PE-53115, or Renco part #RL2445.

3. Output Capacitor Selection (C_{OUT}) A. The value of the output capacitor together with the inductor defines the dominate pole-pair of the switching regulator loop. For stable operation, the capacitor must satisfy the following requirement:

$$C_{OUT} \geq \frac{10 \ \mu F}{3 \ V} \ \mu F$$

For acceptable output ripple voltage, a rating of 100 $\mu F$ or more is recommended. Higher voltage electrolytic capacitors generally have lower ESR numbers, and for this reason it may be necessary to select a capacitor rate for a higher voltage than would normally be needed.

4. Catch Diode Selection (D1) A. The catch-diode current rating must be at least 1.2 times greater than the maximum load current. Also, if the power supply design must withstand a continuous output short, the diode should have a current rating equal to the maximum current limit of the LM2576. The most stressful condition for this diode is an overload or shorted output. See diode selection guide in Figure 8. B. The reverse voltage rating of the diode should be at least 1.25 times the maximum input voltage.

5. Input Capacitor (C_{IN}) An aluminum or tantalum electrolytic bypass capacitor located close to the regulator is needed for stable operation.

To further simplify the buck regulator design procedure, National Semiconductor is making available computer design software to be used with the SIMPLE SWITCHER line of switching regulators. Switchers Made Simple (Version 3.3) is available on a (3½”) diskette for IBM compatible computers from a National Semiconductor sales office in your area.
Application Hints

INPUT CAPACITOR (C \text{in})

To maintain stability, the regulator input pin must be bypassed with at least a 100 \mu F electrolytic capacitor. The capacitor’s leads must be kept short, and located near the regulator.

If the operating temperature range includes temperatures below −25°C, the input capacitor value may need to be larger. With most electrolytic capacitors, the capacitance value decreases and the ESR increases with lower temperatures and age. Paralleling a ceramic or solid tantalum capacitor will increase the regulator stability at cold temperatures. For maximum capacitor operating lifetime, the capacitor’s RMS ripple current rating should be greater than...
**Application Hints** (Continued)

\[
1.2 \times \left( \frac{I_{ON}}{T} \right) \times I_{LOAD}
\]

where \( \frac{I_{ON}}{T} = \frac{V_{OUT}}{V_{IN}} \) for a buck regulator

and \( \frac{I_{ON}}{T} = \frac{|V_{OUT}|}{|V_{OUT}| + V_{IN}} \) for a buck-boost regulator.

**INDUCTOR SELECTION**

All switching regulators have two basic modes of operation: continuous and discontinuous. The difference between the two types relates to the inductor current, whether it is flowing continuously, or if it drops to zero for a period of time in the normal switching cycle. Each mode has distinctively different operating characteristics, which can affect the regulator performance and requirements.

The LM2576 (or any of the SIMPLE SWITCHER family) can be used for both continuous and discontinuous modes of operation.

The inductor value selection guides in *Figure 3* through *Figure 7* were designed for buck regulator designs of the continuous inductor current type. When using inductor values shown in the inductor selection guide, the peak-to-peak inductor ripple current will be approximately 20% to 30% of the maximum DC current. With relatively heavy load currents, the circuit operates in the continuous mode (inductor current always flowing), but under light load conditions, the circuit will be forced to the discontinuous mode (inductor current falls to zero for a period of time). This discontinuous mode of operation is perfectly acceptable. For light loads (less than approximately 300 mA) it may be desirable to operate the regulator in the discontinuous mode, primarily because of the lower inductor values required for the discontinuous mode.

The selection guide chooses inductor values suitable for continuous mode operation, but if the inductor value chosen is prohibitively high, the designer should investigate the possibility of discontinuous operation. The computer design software *Switchers Made Simple* will provide all component values for discontinuous (as well as continuous) mode of operation.

Inductors are available in different styles such as pot core, toroid, E-frame, bobbin core, etc., as well as different core materials, such as ferrites and powdered iron. The least expensive, the bobbin core type, consists of wire wrapped on a ferrite rod core. This type of construction makes for an inexpensive inductor, but since the magnetic flux is not completely contained within the core, it generates more electromagnetic interference (EMI). This EMI can cause problems in sensitive circuits, or can give incorrect scope readings because of induced voltages in the scope probe.

The inductors listed in the selection chart include ferrite pot core construction for AIE, powdered iron toroid for Pulse Engineering, and ferrite bobbin core for Renco.

An inductor should not be operated beyond its maximum rated current because it may saturate. When an inductor begins to saturate, the inductance decreases rapidly and the inductor begins to look mainly resistive (the DC resistance of the winding). This will cause the switch current to rise very rapidly. Different inductor types have different saturation characteristics, and this should be kept in mind when selecting an inductor.

The inductor manufacturer’s data sheets include current and energy limits to avoid inductor saturation.

**INDUCTOR RIPPLE CURRENT**

When the switcher is operating in the continuous mode, the inductor current waveform ranges from a triangular to a sawtooth type of waveform (depending on the input voltage). For a given input voltage and output voltage, the peak-to-peak amplitude of this inductor current waveform remains constant. As the load current rises or falls, the entire sawtooth current waveform also rises or falls. The average DC value of this waveform is equal to the DC load current (in the buck regulator configuration).

If the load current drops to a low enough level, the bottom of the sawtooth current waveform will reach zero, and the switcher will change to a discontinuous mode of operation. This is a perfectly acceptable mode of operation. Any buck switching regulator (no matter how large the inductor value is) will be forced to run discontinuous if the load current is light enough.

**OUTPUT CAPACITOR**

An output capacitor is required to filter the output voltage and is needed for loop stability. The capacitor should be located near the LM2576 using short pc board traces. Standard aluminum electrolytics are usually adequate, but low ESR types are recommended for low output ripple voltage and good stability. The ESR of a capacitor depends on many factors, some which are: the value, the voltage rating, physical size and the type of construction. In general, low value or low voltage (less than 12V) electrolytic capacitors usually have higher ESR numbers.

The amount of output ripple voltage is primarily a function of the ESR (Equivalent Series Resistance) of the output capacitor and the amplitude of the inductor ripple current (\( \Delta I_{IND} \)). See the section on inductor ripple current in Application Hints.

The lower capacitor values (220 µF–1000 µF) will allow typically 50 mV to 150 mV of output ripple voltage, while larger-value capacitors will reduce the ripple to approximately 20 mV to 50 mV.

**Output Ripple Voltage = (\( \Delta I_{IND} \)) (ESR of C_{OUT})**

To further reduce the output ripple voltage, several standard electrolytic capacitors may be paralleled, or a higher-grade capacitor may be used. Such capacitors are often called “high-frequency,” “low-inductance,” or “low-ESR.” These will reduce the output ripple to 10 mV or 20 mV. However, when operating in the continuous mode, reducing the ESR below 0.03Ω can cause instability in the regulator.

Tantalum capacitors can have a very low ESR, and should be carefully evaluated if it is the only output capacitor. Because of their good low temperature characteristics, a tantalum can be used in parallel with aluminum electrolytics, with the tantalum making up 10% or 20% of the total capacitance.

The capacitor’s ripple current rating at 52 kHz should be at least 50% higher than the peak-to-peak inductor ripple current.
Application Hints (Continued)

**CATCH DIODE**

Buck regulators require a diode to provide a return path for the inductor current when the switch is off. This diode should be located close to the LM2576 using short leads and short printed circuit traces.

Because of their fast switching speed and low forward voltage drop, Schottky diodes provide the best efficiency, especially in low output voltage switching regulators (less than 5V). Fast-Recovery, High-Efficiency, or Ultra-Fast Recovery diodes are also suitable, but some types with an abrupt turn-off characteristic may cause instability and EMI problems. A fast-recovery diode with soft recovery characteristics is a better choice. Standard 60 Hz diodes (e.g., 1N4001 or 1N5400, etc.) are also not suitable. See Figure 8 for Schottky and “soft” fast-recovery diode selection guide.

**OUTPUT VOLTAGE RIPPLE AND TRANSIENTS**

The output voltage of a switching power supply will contain a sawtooth ripple voltage at the switcher frequency, typically about 1% of the output voltage, and may also contain short voltage spikes at the peaks of the sawtooth waveform.

The output ripple voltage is due mainly to the inductor sawtooth ripple current multiplied by the ESR of the output capacitor. (See the inductor selection in the application hints.)

The voltage spikes are present because of the fast switching action of the output switch, and the parasitic inductance of the output filter capacitor. To minimize these voltage spikes, special low inductance capacitors can be used, and their lead lengths must be kept short. Wiring inductance, stray capacitance, as well as the scope probe used to evaluate these transients, all contribute to the amplitude of these spikes.

An additional small LC filter (20 µH & 100 µF) can be added to the output (as shown in Figure 13) to further reduce the amount of output ripple and transients. A 10 x reduction in output ripple voltage and transients is possible with this filter.

**FEEDBACK CONNECTION**

The LM2576 (fixed voltage versions) feedback pin must be wired to the output voltage point of the switching power supply. When using the adjustable version, physically locate both output voltage programming resistors near the LM2576 to avoid picking up unwanted noise. Avoid using resistors greater than 100 kΩ because of the increased chance of noise pickup.

**ON/OFF INPUT**

For normal operation, the ON/OFF pin should be grounded or driven with a low-level TTL voltage (typically below 1.6V). To put the regulator into standby mode, drive this pin with a high-level TTL or CMOS signal. The ON/OFF pin can be safely pulled up to +VIN without a resistor in series with it. The ON/OFF pin should not be left open.

**GROUNDING**

To maintain output voltage stability, the power ground connections must be low-impedance (see Figure 2). For the 5-lead TO-220 and TO-263 style package, both the tab and pin 3 are ground and either connection may be used, as they are both part of the same copper lead frame.

**HEAT SINK/ THERMAL CONSIDERATIONS**

In many cases, only a small heat sink is required to keep the LM2576 junction temperature within the allowed operating range. For each application, to determine whether or not a heat sink will be required, the following must be identified:

1. Maximum ambient temperature (in the application).
3. Maximum allowed junction temperature (125˚C for the LM2576). For a safe, conservative design, a temperature approximately 15˚C cooler than the maximum temperatures should be selected.
4. LM2576 package thermal resistances θJA and θJC.

Total power dissipated by the LM2576 can be estimated as follows:

\[ P_D = (V_{IN})(I_Q) + (V_O/V_{IN})(I_{LOAD})(V_{SAT}) \]

where I_Q (quiescent current) and V_{SAT} can be found in the Characteristic Curves shown previously. V_{IN} is the applied minimum input voltage, V_O is the regulated output voltage, and I_{LOAD} is the load current. The dynamic losses during turn-on and turn-off are negligible if a Schottky type catch diode is used.

When no heat sink is used, the junction temperature rise can be determined by the following:

\[ ΔT_J = (P_D)(θ_{JA}) \]

To arrive at the actual operating junction temperature, add the junction temperature rise to the maximum ambient temperature.

\[ T_J = ΔT_J + T_A \]

If the actual operating junction temperature is greater than the selected safe operating junction temperature determined in step 3, then a heat sink is required.

When using a heat sink, the junction temperature rise can be determined by the following:

\[ ΔT_J = (P_D)(θ_{JC} + θ_{Interface} + θ_{Heat Sink}) \]

The operating junction temperature will be:

\[ T_J = T_A + ΔT_J \]

As above, if the actual operating junction temperature is greater than the selected safe operating junction temperature, then a larger heat sink is required (one that has a lower thermal resistance).

Included on the Switcher Made Simple design software is a more precise (non-linear) thermal model that can be used to determine junction temperature with different input-output parameters or different component values. It can also calculate the heat sink thermal resistance required to maintain the regulators junction temperature below the maximum operating temperature.

**Additional Applications**

**INVERTING REGULATOR**

Figure 10 shows a LM2576-12 in a buck-boost configuration to generate a negative 12V output from a positive input voltage. This circuit bootstraps the regulator’s ground pin to the negative output voltage, then by grounding the feedback pin, the regulator senses the inverted output voltage and regulates it to −12V.

For an input voltage of 12V or more, the maximum available output current in this configuration is approximately 700 mA. At lighter loads, the minimum input voltage required drops to approximately 4.7V.
Additional Applications (Continued)

The switch currents in this buck-boost configuration are higher than in the standard buck-mode design, thus lowering the available output current. Also, the start-up input current of the buck-boost converter is higher than the standard buck-mode regulator, and this may overload an input power source with a current limit less than 5A. Using a delayed turn-on or an undervoltage lockout circuit (described in the next section) would allow the input voltage to rise to a high enough level before the switcher would be allowed to turn on.

Because of the structural differences between the buck and the buck-boost regulator topologies, the buck regulator design procedure section cannot be used to select the inductor or the output capacitor. The recommended range of inductor values for the buck-boost design is between 68 µH and 220 µH, and the output capacitor values must be larger than what is normally required for buck designs. Low input voltages or high output currents require a large value output capacitor (in the thousands of micro Farads).

The peak inductor current, which is the same as the peak switch current, can be calculated from the following formula:

\[ I_p \approx \frac{I_{LOAD}}{V_{IN}} \left( \frac{V_{IN} + |V_O|}{V_{IN}} + \frac{V_{IN} |V_O|}{V_{IN} + |V_O|} \right) \times \frac{1}{2L_i f_{osc}} \]

Where \( f_{osc} = 52 \text{ kHz} \). Under normal continuous inductor current operating conditions, the minimum \( V_{IN} \) represents the worst case. Select an inductor that is rated for the peak current anticipated.

The peak inductor current, which is the same as the peak switch current, can be calculated from the following formula:

\[ I_p \approx \frac{I_{LOAD}}{V_{IN}} \left( \frac{V_{IN} + |V_O|}{V_{IN}} + \frac{V_{IN} |V_O|}{V_{IN} + |V_O|} \right) \times \frac{1}{2L_i f_{osc}} \]

Where \( f_{osc} = 52 \text{ kHz} \). Under normal continuous inductor current operating conditions, the minimum \( V_{IN} \) represents the worst case. Select an inductor that is rated for the peak current anticipated.

\[ I_p \approx \frac{I_{LOAD}}{V_{IN}} \left( \frac{V_{IN} + |V_O|}{V_{IN}} + \frac{V_{IN} |V_O|}{V_{IN} + |V_O|} \right) \times \frac{1}{2L_i f_{osc}} \]

Where \( f_{osc} = 52 \text{ kHz} \). Under normal continuous inductor current operating conditions, the minimum \( V_{IN} \) represents the worst case. Select an inductor that is rated for the peak current anticipated.

Because of the boosting function of this type of regulator, the switch current is relatively high, especially at low input voltages. Output load current limitations are a result of the maximum current rating of the switch. Also, boost regulators cannot provide current limiting load protection in the event of a shorted load, so some other means (such as a fuse) may be necessary.

**UNDERSURGE LOCKOUT**

In some applications it is desirable to keep the regulator off until the input voltage reaches a certain threshold. An undervoltage lockout circuit which accomplishes this task is shown in Figure 12, while Figure 13 shows the same circuit applied to a buck-boost configuration. These circuits keep the regulator off until the input voltage reaches a predetermined level:

\[ V_{TH} = V_{Z1} + 2V_{BE}(Q1) \]

**FIGURE 11. Negative Boost**

Because of the boosting function of this type of regulator, the switch current is relatively high, especially at low input voltages. Output load current limitations are a result of the maximum current rating of the switch. Also, boost regulators cannot provide current limiting load protection in the event of a shorted load, so some other means (such as a fuse) may be necessary.

These circuits keep the regulator off until the input voltage reaches a predetermined level:

\[ V_{TH} = V_{Z1} + 2V_{BE}(Q1) \]

**FIGURE 12. Undervoltage Lockout for Buck Circuit**
Additional Applications (Continued)

DELAYED STARTUP
The ON/OFF pin can be used to provide a delayed startup feature as shown in Figure 14. With an input voltage of 20V and for the part values shown, the circuit provides approximately 10 ms of delay time before the circuit begins switching. Increasing the RC time constant can provide longer delay times. But excessively large RC time constants can cause problems with input voltages that are high in 60 Hz or 120 Hz ripple, by coupling the ripple into the ON/OFF pin.

ADJUSTABLE OUTPUT, LOW-RIPPLE POWER SUPPLY
A 3A power supply that features an adjustable output voltage is shown in Figure 15. An additional L-C filter that reduces the output ripple by a factor of 10 or more is included in this circuit.

Definition of Terms

BUCK REGULATOR
A switching regulator topology in which a higher voltage is converted to a lower voltage. Also known as a step-down switching regulator.

BUCK-BOOST REGULATOR
A switching regulator topology in which a positive voltage is converted to a negative voltage without a transformer.

DUTY CYCLE (D)
Ratio of the output switch's on-time to the oscillator period.

for buck regulator \[ D = \frac{t_{ON}}{T} = \frac{V_{OUT}}{V_{IN}} \]

for buck-boost regulator \[ D = \frac{t_{ON}}{T} = \frac{|V_{O}|}{|V_{O}| + V_{IN}} \]

CATCH DIODE OR CURRENT STEERING DIODE
The diode which provides a return path for the load current when the LM2576 switch is OFF.

EFFICIENCY (\(\eta\))
The proportion of input power actually delivered to the load.

\[ \eta = \frac{P_{OUT}}{P_{IN}} = \frac{P_{OUT}}{P_{OUT} + P_{LOSS}} \]
Definition of Terms (Continued)

CAPACITOR EQUIVALENT SERIES RESISTANCE (ESR)
The purely resistive component of a real capacitor's impedance (see Figure 16). It causes power loss resulting in capacitor heating, which directly affects the capacitor's operating lifetime. When used as a switching regulator output filter, higher ESR values result in higher output ripple voltages.

EQUIVALENT SERIES INDUCTANCE (ESL)
The pure inductance component of a capacitor (see Figure 16). The amount of inductance is determined to a large extent on the capacitor's construction. In a buck regulator, this unwanted inductance causes voltage spikes to appear on the output.

OUTPUT RIPPLE VOLTAGE
The AC component of the switching regulator’s output voltage. It is usually dominated by the output capacitor's ESR multiplied by the inductor’s ripple current ($\Delta I_{\text{ind}}$). The peak-to-peak value of this sawtooth ripple current can be determined by reading the Inductor Ripple Current section of the Application hints.

CAPACITOR RIPPLE CURRENT
RMS value of the maximum allowable alternating current at which a capacitor can be operated continuously at a specified temperature.

STANDBY QUIESCENT CURRENT ($I_{\text{standby}}$)
Supply current required by the LM2576 when in the standby mode (ON/OFF pin is driven to TTL-high voltage, thus turning the output switch OFF).

INDUCTOR RIPPLE CURRENT ($\Delta I_{\text{ind}}$)
The peak-to-peak value of the inductor current waveform, typically a sawtooth waveform when the regulator is operating in the continuous mode (vs. discontinuous mode).

CONTINUOUS/DISCONTINUOUS MODE OPERATION
Relates to the inductor current. In the continuous mode, the inductor current is always flowing and never drops to zero, vs. the discontinuous mode, where the inductor current drops to zero for a period of time in the normal switching cycle.

INDUCTOR SATURATION
The condition which exists when an inductor cannot hold any more magnetic flux. When an inductor saturates, the inductor appears less inductive and the resistive component dominates. Inductor current is then limited only by the DC resistance of the wire and the available source current.

OPERATING VOLT MICROSECOND CONSTANT ($E \cdot T_{\text{op}}$)
The product (in Volt·µs) of the voltage applied to the inductor and the time the voltage is applied. This $E \cdot T_{\text{op}}$ constant is a measure of the energy handling capability of an inductor and is dependent upon the type of core, the core area, the number of turns, and the duty cycle.
